Key Challenges in Modeling Wind and Other Variable Sources in Expansion Planning

- How to properly represent and model their:
 - Uncertainty
 - Variability

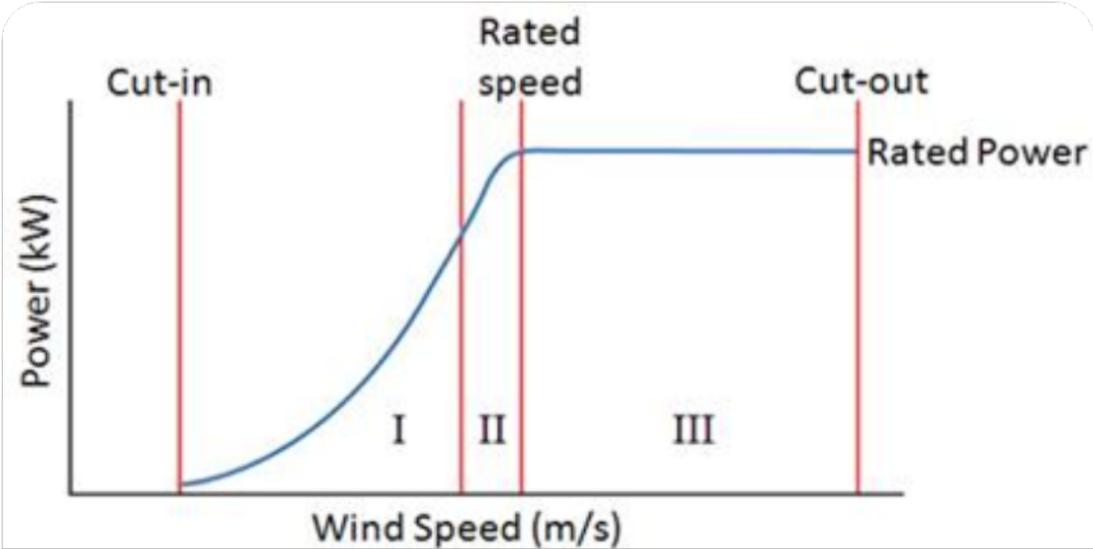

Wind Plant Characterization

Example: Wind Turbine Vensys 77 (1.5 MW)

Power Curve

| Wind speed (m/s) | Power (kW) |
|------------------|------------|
| 0 | 0 |
| 3 | 21.9 |
| 4 | 75.1 |
| 5 | 155.8 |
| 6 | 274.3 |
| 7 | 439.3 |
| 8 | 668 |
| 9 | 932.1 |
| 10 | 1215.4 |
| 11 | 1418.2 |
| 12 | 1473.7 |
| 13 | 1496.5 |
| 14 | 1500 |
| 15 | 1500 |
| 16 | 1500 |
| 17 | 1500 |
| 18 | 1500 |
| 19 | 1500 |
| 20 | 1500 |
| 21 | 1500 |
| 22 | 1500 |

Cut-in wind speed: 3.0 m/s
Cut-out wind speed: 22 m/s

Wind Speed Characterization

Historical Wind Speed:

| Date | Hour | 70m Wind speed mph |
|----------|------|--------------------|
| 1-Sep-06 | 0 | 7.10 |
| | 1 | 8.10 |
| | 2 | 6.78 |
| | 3 | 7.37 |
| | 4 | 6.47 |
| | 5 | 6.83 |
| | 6 | 8.82 |
| | 7 | 9.12 |
| | 8 | 8.40 |
| | 9 | 7.75 |
| | 10 | 9.90 |
| | 11 | 8.12 |
| | 12 | 10.63 |
| | 13 | 10.92 |
| | 14 | 11.32 |
| | 15 | 10.42 |
| | 16 | 13.27 |
| | 17 | 11.48 |
| | 18 | 12.12 |
| | 19 | 11.55 |
| | 20 | 12.48 |
| | 21 | 11.82 |
| | 22 | 11.05 |
| | 23 | 9.22 |

Wind Speed Models:

Weibull Distribution

$$f(x; \lambda, k) = \begin{cases} \frac{k}{\lambda} \left(\frac{x}{\lambda}\right)^{k-1} e^{-(x/\lambda)^k} & x \geq 0 \\ 0 & x < 0 \end{cases}$$

Time Series

$$X_t = c + \sum_{i=1}^p \varphi_i X_{t-i} + \varepsilon_t$$

Markov Chains, etc.

From Wind Speed to Wind Power

Power Curve

| Wind speed (m/s) | Power (kW) |
|------------------|------------|
| 0 | 0 |
| 3 | 21.9 |
| 4 | 75.1 |
| 5 | 155.8 |
| 6 | 274.3 |

What is the Capacity Value of a Wind Plant?

- Utilities use different approaches to estimate the capacity value (capacity credit or firm power) of wind plants
- First we need to distinguish whether capacity credit is determined for planning or operation purposes:

Long-Term Expansion Planning:

- The long-term capacity credit is usually linked to how much of new conventional generating capacity additions can be replaced by the wind plant
- The overall availability of wind plant (e.g., capacity factor) is one of the key factors influencing the capacity value of wind plant in the long term

Operations Planning:

- In operations planning, the capacity credit is related to how much wind capacity will be available for meeting the load next day, especially during the peak hours
- Good wind forecasting plays a key role in determining the wind capacity credit in the short term

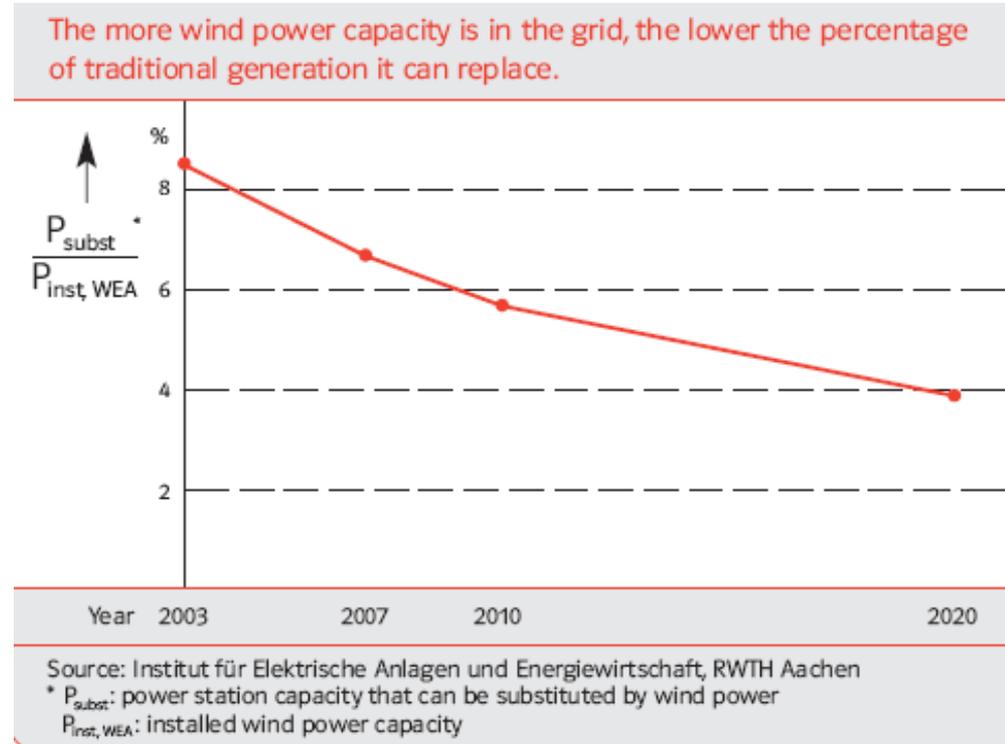

Wind Capacity Credit and System Reliability

- Reliability of system operation is one of important aspects for determining both short- and long-term capacity credits
- Although the operational availability of a wind turbine may be very high, it will not operate when there is no wind, which makes it a relatively unreliable generation source
- The concept of Equivalent Load-Carrying Capacity (ELCC) is often used to determine the capacity credit of wind farms in the long term
- The ELCC method is based on the LOLP measure of system reliability so that a wind farm is benchmarked against an ideal, perfectly reliable unit with 100% availability
- The amount of perfectly reliable capacity that achieves the same system reliability as in the case with wind plant determines the ELCC of a wind plant
- A related “equivalent capacity” approach is to use an alternative conventional unit (e.g., gas turbine) instead of the ideal unit
- The equivalent unit is sized so that the system LOLP is the same if calculated with a wind plant instead of the gas plant

ELCC Decreases with Higher Penetration of Wind Capacity in the System

- German utility E.ON: “The more wind power capacity is on the grid, the lower the percentage of traditional generation it can replace.”
 - Firm capacity from wind in 2007: about 7% of installed capacity
 - Firm capacity in 2020 is expected to drop to 4%.

Source: E.ON Wind Report 2005

Benefits of Wind Power

- Energy Credits
 - Energy generation + fuel savings
- Capacity Credits
 - Capacity value or ELCC
- Emission Credits
 - Reduced overall pollutant emissions in the system

Calculation of Wind Power Benefits in the Long Term

- Economic cost/benefit analysis
- Usually performed over the lifetime of a wind farm
- Calculations performed in terms of net present value

Long-Term Benefits of Wind Power Can Be Calculated using Capacity Expansion Models

- The objective of models for optimal capacity expansion, such as WASP-IV, is to determine the least-cost system expansion plan that would meet the demand over the study period, while satisfying all reliability and other constraints specified by user
- The operating and investment costs, determined by the model, can be used to calculate energy and capacity credits of wind plants
- The emissions of various pollutants calculated by the model can be used to determine the emission credits

Calculation of Long-Term Benefits of Wind Power using a Capacity Expansion Model

- Typically, the analysis is performed for two scenarios:
 - Case without wind power (Reference Case)
 - Case with the wind power capacity
- System reliability (e.g., LOLP and ENS) should be kept at approximately the same level in both scenarios
- The analysis can be performed either for a specific wind farm or for a given penetration of wind farm capacity over the study period

Comparison of Results for Two Scenarios

- **Energy credits** can be calculated from the differences in operating costs
- **Capacity credits** can be calculated from the differences in expansion schedules:
 - The amount of conventional capacity (MW) displaced or deferred by wind farms
 - Savings in the investment costs (\$) for new generating capacity can also be calculated
- **Emission credits** can be calculated from the differences in air emissions

Representation of Wind Power in Capacity Expansion Models

- There are several approaches for modeling wind power in expansion planning models:
 1. Load Modification Approach (“Negative Load” approach)
 2. Supply-Side Approach (wind is treated as conventional power plant)
 - i. Run-of-river hydro capacity
 - ii. Unreliable thermal capacity
 3. Multi-Block Probabilistic Simulation Approach

Representation of Wind Power as Negative Load

Advantages:

- a) Chronological information of wind speed is maintained
- b) The approach captures variability of wind power
- c) Appropriate for short-term studies (for best results, the wind generation pattern should be “typical”)

Disadvantages:

- a) Does not capture uncertainty (assumes the same chronological wind pattern in the future)
- b) When simulated wind speed is used, zero wind power is averaged out
- c) Could provide inaccurate results for long-term studies

Supply-Side Approach

**Available plant generation =
Wind generation**

Advantages:

- a) Wind power is treated as conventional run-of-river hydro or unreliable thermal power plant
- b) The wind plant is used in dispatch simulations and reliability calculations
- c) The approach captures some variability and some uncertainty
- d) Appropriate for long-term studies

Disadvantages:

- a) Stochastic nature of wind power (zero-rated capacity) is misrepresented
- b) Chronological hourly wind information is not captured (not a concern for long-term studies)

Supply-Side Approach: Representation of Wind Power as Run-of-River Hydro Plant

- Wind generation has some similarities with run-of-river hydro generation:
 - Both are non-dispatchable (power has to be used when produced)
 - Both can have seasonal variations
 - Both are characterized by a level of uncertainty (wind conditions or hydrological conditions)
 - There is practically no energy storage available
- If a capacity expansion model allows for multiple hydrological conditions, these can also be used to express the probabilities of expected wind generation
- Using the modeling of run-of-river hydro, specify the expected wind generation and available capacity by period, according to their probabilities of occurrence
- Both existing and candidate wind plants can be represented

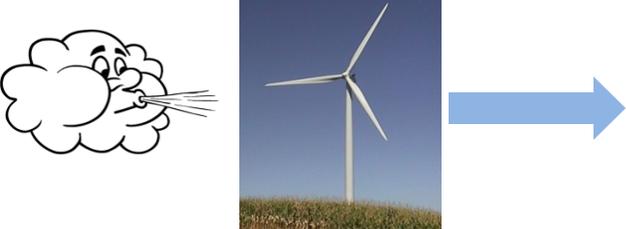

Supply-Side Approach: Representation of Wind Power as Unreliable Thermal Generating Capacity

- Simple and easy approach, both existing and candidate wind farms can be represented
- Wind farm is represented as very unreliable thermal generating unit
- The forced outage rate of the thermal unit should be specified high (thermal unit generation should match the expected generation from the wind farm)
- Since wind farms operate throughout the year, there should be no maintenance requirements for the fictitious thermal unit
- Fuel costs can be specified as zero, while O&M costs should correspond to the real O&M costs of the wind farm
- Since the running costs of this unit are very low or zero, the wind farm will always be loaded when available

Multi-Block Probabilistic Simulation Approach

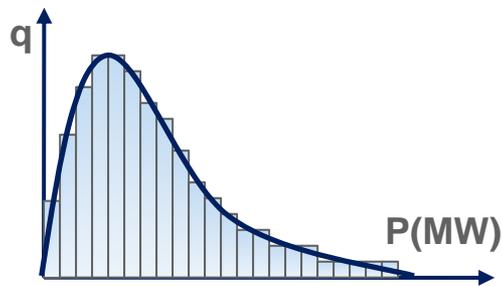

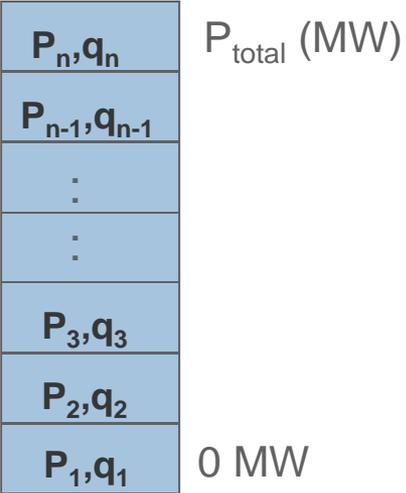

Power blocks and probabilities

Advantages:

- a) Wind power is treated as conventional power plant with a number of capacity blocks
- b) Stochastic nature of wind power (zero-rated capacity) is represented
- c) Probability distribution addresses both the variability and uncertainty of wind power
- d) Wind plant is convolved into probabilistic dispatch and reliability calculation
- e) Appropriate for long-term studies

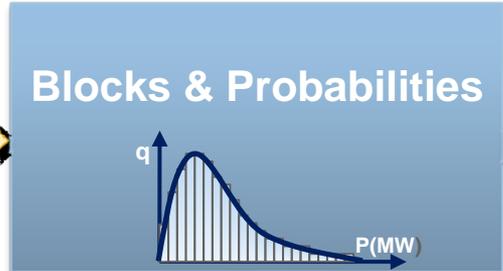

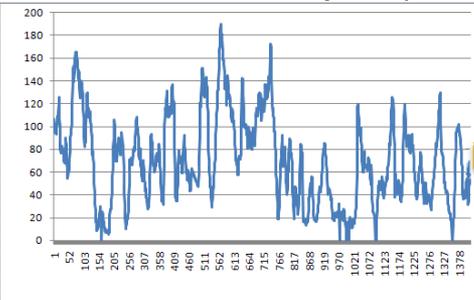

Disadvantages:

- a) Chronological hourly wind information is not captured (not a concern for long-term studies)

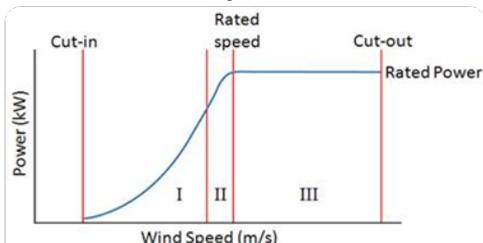

Implementation of Multi-Block Approach

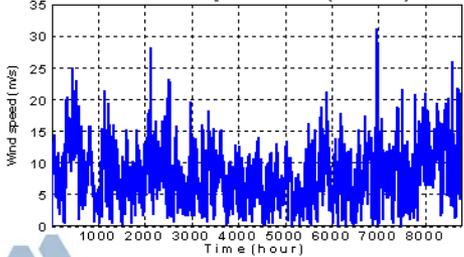

Wind Power Output (MW)

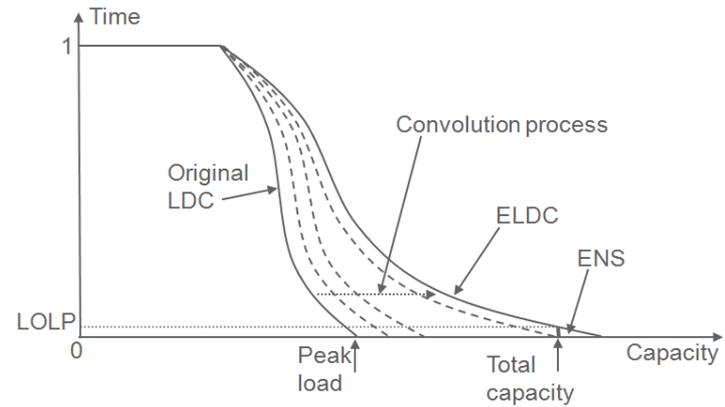

Power Output Curve

Wind speed (m/s)

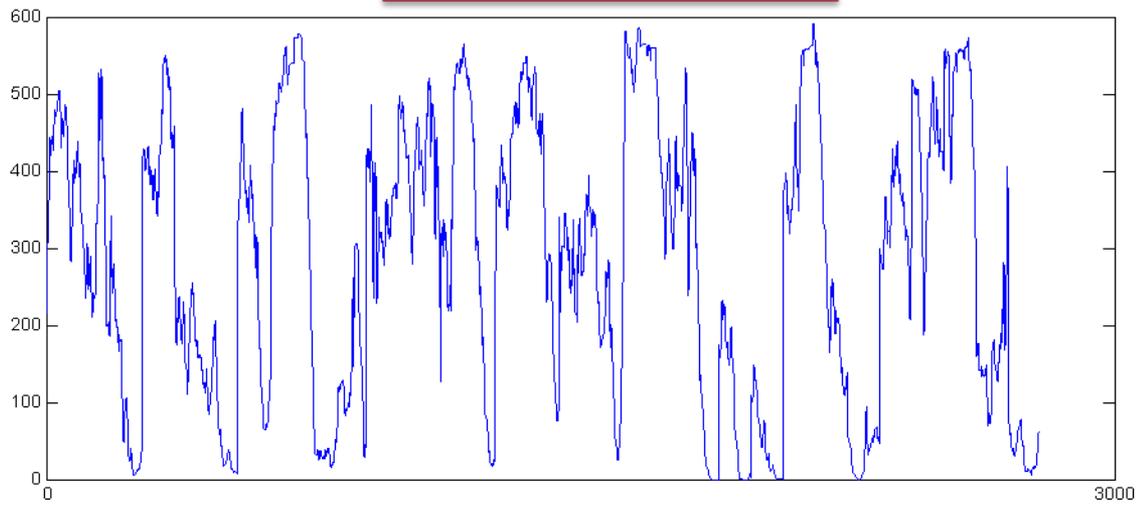

| | |
|--------------------|------------------|
| P_n, q_n | P_{total} (MW) |
| P_{n-1}, q_{n-1} | |
| \vdots | |
| \vdots | |
| P_3, q_3 | |
| P_2, q_2 | |
| P_1, q_1 | 0 MW |

Wind Capacity Blocks and Their Probabilities Can Be Determined using a Wind Power Stochastic Model

Wind power (MW)

Mean = 284.1
St. dev. = 182.1

Blocks & Probabilities

| <i>n</i> | Range | Average Value | Probability |
|----------|---------|---------------|-------------|
| 0 | 0 | 0 | 0.0143 |
| 1 | 0-60 | 30 | 0.1652 |
| 2 | 60-120 | 90 | 0.0756 |
| 3 | 120-180 | 150 | 0.0821 |
| 4 | 180-240 | 210 | 0.0792 |
| 5 | 240-300 | 270 | 0.0792 |
| 6 | 300-360 | 330 | 0.1047 |
| 7 | 360-420 | 390 | 0.1190 |
| 8 | 420-480 | 450 | 0.0986 |
| 9 | 480-540 | 510 | 0.0946 |
| 10 | 540-600 | 570 | 0.0875 |

Mean = 285.5
St. dev. = 181.2

Data Processing for Multi-Block Approach

Example:

Wind speed (m/s)

| Date | Hour | 70m Wind speed (m/s) |
|----------|------|----------------------|
| 1-Sep-06 | 0 | 7.10 |
| | 1 | 8.10 |

Wind Farm (6 MW)

| Block | Power Output | Probability |
|-------|--------------|-------------|
| 0 | 0 | 0.1306 |
| 1 | 0.6 | 0.1204 |
| 2 | 1.2 | 0.2056 |
| 3 | 1.8 | 0.1194 |
| 4 | 2.4 | 0.0278 |
| 5 | 3 | 0.1042 |
| 6 | 3.6 | 0.0602 |
| 7 | 4.2 | 0.1000 |
| 8 | 4.8 | 0.0167 |
| 9 | 5.4 | 0.0306 |
| 10 | 6 | 0.0847 |

Wind Power Aggregation

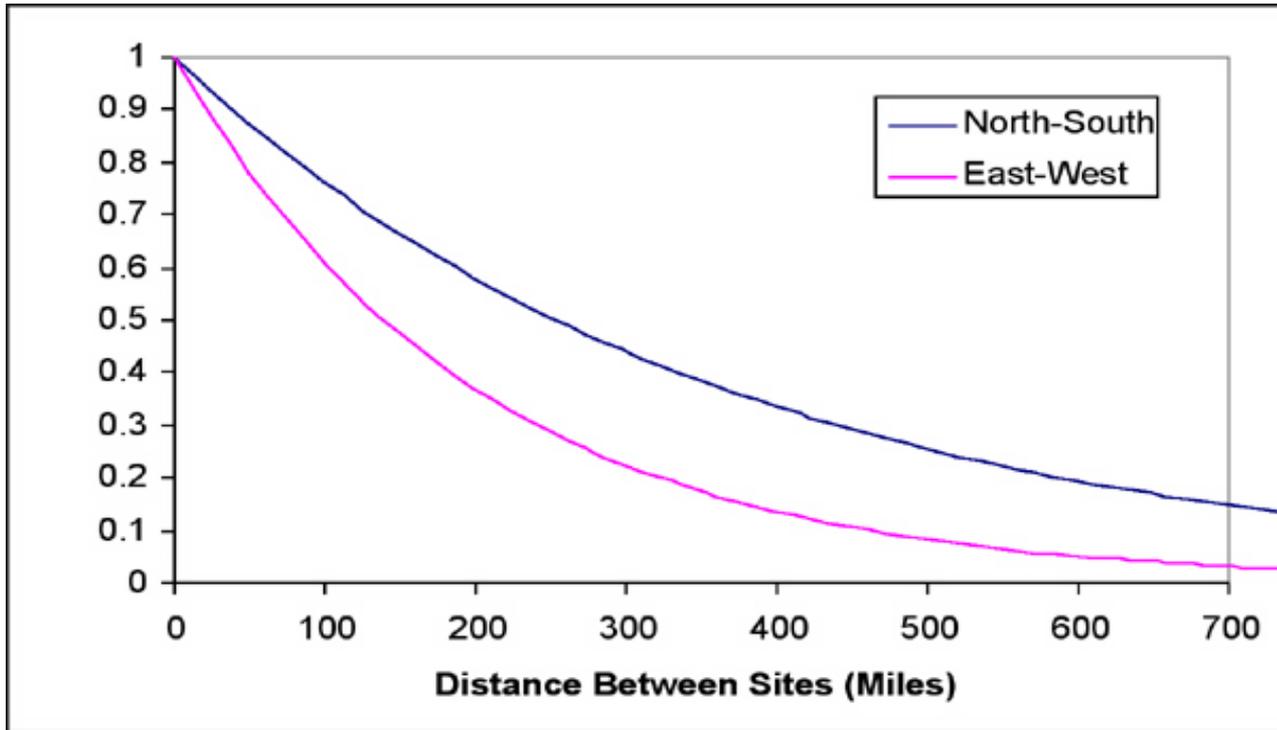

Blocks & Probabilities

| | |
|--------------------|------------------|
| P_n, q_n | P_{total} (MW) |
| P_{n-1}, q_{n-1} | |
| \vdots | |
| \vdots | |
| P_3, q_3 | |
| P_2, q_2 | |
| P_1, q_1 | 0 MW |

Wind Farm Correlation

Source: NREL

- Correlation in wind farm power output is decreasing with the distance between the wind farms
- In the US, correlation factors are different for N-S and E-W directions
