MISO R&D on Improving Market Clearing Software for Future Market Enhancements

FERC Technical Conference on Increasing Real-Time and Day-Ahead Market Efficiency through Improved Software
June 26-28, 2018

Yonghong Chen  Consulting Advisor, Market R&D, MISO
Jessica Harrison  Director, Market R&D, MISO
Overview of MISO R&D on future market clearing software

Resource modeling and mathematical formulation

- Enhanced hybrid combined cycle modeling
- Startup and transition trajectories
- Future resource analysis: storage, hybrid plants, DER, VPP, etc.
- Improve computational performance as well as price efficiency through tighter mathematical formulation
- Study on market clearing and pricing under future resource portfolio

Deliverability for energy and reserves & uncertainty management

- Co-optimized formulation for reserve deliverability
- Uncertainty management

Solution approaches

- Enhance the interaction with existing commercial solvers
- Develop high-performance computing based next generation optimization engine under the ARPA-E HIPPO project
MISO strives for enhanced performance of market clearing results as we continue to grow in size and complexity.

R&D has contributed greatly to advancing the market clearing software performance and overall market efficiency.
R&D has been addressing Day Ahead computational challenges

- Delivered
- Upcoming delivery
- POC with vendors
- ARPA-E project

New heuristic approaches
- Improve MIP formulation

Efficient iteration between Optimization and Network Analysis

Incorporate VLR constraints to reduce out of market commitment

Incremental solve capability
- Commit reason identification
- Solution polishing

Constraint and variable hints to MIP solver

Parallel computing and HPC

Efficient iteration between Optimization and Network Analysis

OPERATOR CASE PREPARATION, OUT-OF-MARKET COMMITMENT AND SOLUTION ANALYSIS & IMM CASE ADJUSTMENTS

USER INTERACTION

MARKET CLEARING ENGINE (GE/IBM-SOLVER)

OPTIMIZATION ENGINE
- UNIT COMMITMENT & ECONOMIC DISPATCH
- NETWORK & SECURITY ANALYSIS

DA MARKET CLEARING RESULTS

a. Delivered; b. Upcoming delivery; c. POC with vendors; d. ARPA-E project
MISO is preparing for the future …

Enhancements in Resource Modeling

• The most complicated existing resource model: configuration-based combined cycle
  – Dedicated R&D on DA performance from 2013-2016\textsuperscript{[1,2]}
  
  SCUC formulation improvement
  – Convex envelope cost function
  – Condensed transmission matrix modeling
  – Tighter and more compact ECC model

  - 30% reduction in production MIP solving time
  - 37% reduction in DA one-pass solving time
  - 66% reduction on MIP with prototype ECC model

– Estimated $34 million annual benefit
– On-going Enhanced Combined Cycle Task Team on Conceptual Design for implementation

Further research on combined cycle

- Hybrid configuration and component model\textsuperscript{[3]}
  - Most constraints can be properly modeled on the configuration level (e.g., 1CT+1ST, 2CT+1ST+DB)
  - Mapping between configurations and components to allow constraints such as minimum run time, minimum down time to be modeled on physical component (e.g., CT, ST or DB)

\[ \text{Better reflect physical constraints and supported by participants} \]

Developed with Clarkson University and GE

Further research on combined cycle (Cont.)

Tighter formulation to improve SCUC performance and ELMP approximation

- Multi-interval integer relaxation to approximate full ELMP
- Multi-interval ELMP (future pricing design improvement option)
- Single interval approximation (near term ECC design option)
- Single interval approximation
- How to amortize transition cost? How to properly handle transition?

Incorporate transition curve into SCUC, SCED and pricing

On going R&D with University of Texas – Austin (see presentation on this topic for details)

| transition | 1x1→2x1=0.2 |

- ELMP would be driven by:
  - Transition cost
  - “From configuration” incremental energy cost
  - “To configuration” incremental energy cost
- Transition trajectory may have bigger impact on commitment, dispatch and pricing
Research on future resource modeling

MISO uses 8% performance tolerance in part to account for inaccurate resource modeling

- IMM recommendation to tighten the tolerance band
- Configuration-based modeling may be expanded for pumped storage or coal units
  - Applying to too many resources can cause computational difficulty

Future resource challenges

- Resources on different size scale: optimize large generators with small DER/storage/DR
  - MIP gap issue for small resources modeled with integer variables (experience with wind)
  - Density issue for small resources only modeled with continuous variables (experience with small virtuals)

- Aggregation
  - May address small size issue
- Challenge with aggregated resource modeling
- Challenge with transmission constraints
Current commercial and EMS model illustration

LBA1

*Metered tie line & generation to identify balancing area net load.*

LBA2

- **EPNode 1**: 70% \( \rightarrow \) CPNode 1
- **EPNode 2**: 30% \( \rightarrow \) CPNode 2

**Aggregation Factor** = EPNode MW x \% Ownership. May change every interval (topology & load)

- **CPNode 1**: 70% of EPNode 1
- **CPNode 2**: 50% of EPNode 1 & 50% of EPNode 2
- **CPNode 3**: 50% of EPNode 3 & 50% of EPNode 2
- **CPNode 4**: 100% EPNode 4
- **CPNode 5**: 100% EPNode 3 & 100% EPNode 5

**CPNode sensitivity to transmission flow**: May change every interval

**CPnode**:

- **Epnode**: EMS model, net injection and pricing
- **Cpnode**: Ownership, offer, meter and settle

\% of ownership updates quarterly. May change every interval

*Aggregate of household water heaters*

- **Open Breaker**
- **EPNode**
- **CPNode**
DER resource modeling and impact on transmission

“Master Pnode” aggregation formulation on transmission constraints can greatly reduce non-zeros from 10 million to 2-3 million \cite{1}

1) Aggregate resources with the same impacts on transmission constraints together in transmission constraint
2) $P_{min}/P_{max}/$... are still represented separately

Participants may aggregate DERs with different transmission impact together to form an aggregated offer: $P_{min34}/P_{max34}/$...$34$

- How predictable is the aggregation factor (DA, 7-day RAC, LAC, RT-SCED)?
- How to update RTO on the aggregation factor?
- How good is the aggregated offer?
- How to reflect distribution constraints?

Reserve deliverability

• With increased uncertainty, reserve can play more important role

• Existing reserve models may require improvement to properly address deliverability
  – MISO started with define reserve zones and enforce zonal reserve requirement constraints
  – Enforce reserve zone requirement constraints inside SCUC and SCED
  – Count on offline study to provide
    • Reserve zone definition (quarterly update)
    • Minimum zonal reserve requirements (three-day ahead study)
Production issues:

• Difficult to define proper zonal reserve requirements

• When there is enough capacity in a zone:
  • Energy were dispatched down in a zone to relief congestion
  • 600MW (~75%) of spinning reserve was cleared in that zone. Most of the spinning reserve would not be deliverable if deployed
  • Offline study could not predict the issue

• When there is not enough capacity in a zone:
  • In order to clear pre-set zonal reserve requirement, cleared energy in the zone had to be lowered. ➔ Increase in import flow
  • Cleared zonal reserve can provide count flow when deployed. However, the post-deployment flow was not better with the pre-set zonal reserve requirement.
  • MISO had one event with zonal spin scarcity due to the pre-set zonal requirement when the requirement didn’t provide any benefit to post deployment flow.
Post Zonal Reserve Deployment Transmission Constraint

- Solve co-optimized reserve zone requirements (implemented in 2011)\[4\]
  - To deliver reserve within transmission limits on a zonal basis
  - Solve $r_{k,t}^{REG}$, $r_{k,t}^{SPIN}$, $r_{k,t}^{SUPP}$: zonal requirement variable for zone $k'$ within the optimization

- Post-Regulating Reserve Deployment Up and Down Transmission Constraints

\[
F_i^P(p_t, P_t) + \sum_{k \in K} \{r_{k,t}^{REG} \cdot B_{i,k,t}^{REG}\} - B_{i,LC,t} \cdot R_{MKT,t}^{REG} \leq \bar{F}_{i,t} \quad \forall i \in I \quad (1)
\]
\[
F_i^P(p_t, P_t) - \sum_{k \in K} \{r_{k,t}^{REG} \cdot B_{i,k,t}^{REG}\} + B_{i,LC,t} \cdot R_{MKT,t}^{REG} \leq \bar{F}_{i,t} \quad \forall i \in I \quad (2)
\]

Flow from Energy \quad Flow from regulation deployment \quad Flow from load deviation at reference bus (0)

- Post-Contingency Reserve Deployment Transmission Constraints (one for each reserve zone)

\[
F_i^P(p_t, P_t) - E_{k,t} \cdot B_{i,k,t}^{TRIP} + D_{k,t}^{SPIN} \cdot \sum_{k' \in K} \{r_{k',t}^{SPIN} \cdot B_{i,k',t}^{SPIN}\} + D_{k,t}^{SUPP} \cdot \sum_{k' \in K} \{r_{k',t}^{SUPP} \cdot B_{i,k',t}^{SUPP}\} \leq \bar{F}_{i,t} \quad \forall i \in I, \forall k \in K \quad (3)
\]

Proportional deployment factor for largest gen trip in zone $k$, calculated based on “the size of the event” and “system total reserve requirement”
Observations and conclusions from post zonal reserve deployment transmission constraint approach

- Zonal reserve requirement resulted in **spin scarcity without improving post event flow**. LMP didn’t reflect the import congestion.
- Co-optimized SCED can ensure 750 MW post deployment flow primarily through re-dispatch of energy.
- Zonal MCP and LMP differences reflect the impact of both energy and reserve deployment on congestion.

Improvement with post zonal reserve deployment constraints

- Formulation implemented in 2011 was based on proportional contingency reserve deployment

- Considering new formulation that may be extended for other reserve products (e.g., 30-min reserve)

\[
F_{i,t}^P(p_t, P_t) = E_{k,t} \cdot B_{i,k,t}^{TRIP} + \sum_{k \in K} \{r_d_{k,k,t}^{SPIN} \cdot B_{i,k,t}^{SPIN} \} + \sum_{k' \in K} \{r_d_{k,k',t}^{SUPP} \cdot B_{i,k',t}^{SUPP} \} \leq \bar{F}_{i,t}
\]

\[
\sum_{k \in K} r_d_{k,k,t}^{SPIN} = D_{k,t}^{SPIN} \cdot TotalSpin_t, \quad \sum_{k \in K} r_d_{k,k,t}^{SUPP} = D_{k,t}^{SUPP} \cdot TotalSupp_t
\]

\[
r_d_{k,k,t}^{SPIN} \leq r_{k,t}^{SPIN}, \quad r_d_{k,k,t}^{SUPP} \leq r_{k,t}^{SUPP}
\]

\[
\forall i \in I, \forall k', k \in K
\]

\[
r_d_{k,k',t}^{SPIN}, r_d_{k,k',t}^{SUPP} \quad Zone k' deployment variable for largest gen trip in zone k
\]
Future research on managing deliverability and uncertainty

<table>
<thead>
<tr>
<th>Deliverability</th>
</tr>
</thead>
<tbody>
<tr>

<td>• Operators not only need to know the deterministic commitment/dispatch results, but also need to understand the available headroom under various scenarios</td>
</tr>
<tr>
<td>• Better to provide probabilistic indices</td>
</tr>
</tbody>
</table>
Improve price efficiency

Near term: improving single interval ELMP approximation

• Apply convex envelope formulation
• Evaluate fast-start eligibility
• Evaluate regulation eligibility in pricing run

Research on future pricing design

• Renewable study
  • Pricing issues under near zero marginal cost
  • How and to what extend can current single interval ELMP help?
• Multi-interval full ELMP
  • Approximate with solving integer relaxation under convex primal formulation
  • Passing commitment costs through multi-stage processes. How to handle commitment cost incurred in early stages?
    • 7-day RAC → DA → FRAC → IRAC → LAC
    • Rolling RT (commitment from DA/RAC/LAC)
  • Reflect reliability services in the clearing and pricing (e.g., local VAR constraints)
• Other pricing mechanism ?
New solution approaches

Explore parallel computing under ARPA-E HIPPO project

- HIPPO concurrent solver milestones: 2x by 09/2018 and 10x by 09/2019
- ADMM, RINS, partition, tighter formulation, strong branching... (see HIPPO presentations for detail)
  - Upper bound (UB)
    - Several promising methods to achieve 2x
  - Lower bound (LB):
    - LB directly from the MIP solver is sufficiently good for 0.5% MIP gap.
    - Need more improvement on LB in order to reduce time to reach 0.1% MIP gap

- Approach led by MISO: neighborhood search with parallel processors to generate effective hints and speed up solution process (i.e., SCUC polishing)
  - Fix binary and continuous variables
  - Set lazy constraints
  - Fast LP and MIP for solution polishing
  - Extract hints from historical solutions (possibility of using machine learning)
Polishing after 4 iterations compared to Full MIP (polishing gap is calculated with LB from full MIP at 3600s)
