#### Abstract

Executive Summary All power system operators ensure their systems adhere to thermal limits on transmission lines in order to avoid line deformation. Also, thermal limits are used as surrogates for voltage stability. The IEEE test problems do not include data on these limits. The purpose of this paper is to present a simple method for constructing current magnitude constraints and to report on the computational properties in solving the resulting problems. This paper finds limits on the maximum allowable current magnitude that result in a feasible solution for the 14bus, 30 -bus, 57 -bus, and 118 -bus IEEE test problems. For each test problem, one single limit is applied to all lines that makes the optimal solution without these limits infeasible. For each problem we develop a 'tight' and a 'loose' constraint. We solve the resulting problem using the current voltage formulation. Different test problems exhibit different characteristics. Including these constraints in the ACOPF increases the solution time between 2 to 20 times and costs (objective function) up to 25 percent.

## 1. Introduction

The amount of current that can flow through power system transmission assets (referred to here as lines) is limited by thermal restrictions. The thermal ratings of the transmission are functions of the materials that compose the assets. The excessive heat caused by the line current can deform and degrade transmission lines and cause them to sag. Heat losses are proportional to current magnitude squared. In addition, current magnitude constraints are often used as surrogates for other constraints such as voltage stability. However, most IEEE test problems do not include current magnitude limits on the transmission lines even though they are an important aspect in model testing.

In the absence of these constraints, one approach is to put in constraints based on physical characteristics. Often, there is little information about the lines. It takes considerable time to develop constraints based on physical characteristics, and the result may not be binding constraints.

The purpose of this paper is to develop a methodology for creating line current magnitude constraints using a set of the IEEE test problems. We are interested in creating binding constraints based on maximum current magnitude rather than on apparent power on the lines or on voltage angle differences. The approach we employ is to create constraints from the optimal solution without these constraints. With these constraints, the resulting power flow problem has a feasible solution. Subsequent testing helps to understand how constraining the line flows affects the resulting power flow solution and solution time.

## 2. Notation

Variables and parameters are indexed over buses denoted by subscripts $n$ and $m$. Transmission lines are indexed by terminal buses $n$ and $m$ and $k$. For a complex variable or parameter, the superscript $r$ denotes the real portion and the superscript $j$ denotes the imaginary portion. For example, if $x=a+j b, x^{r}=a, x^{j}=b$ where $\boldsymbol{j}=(-1)^{1 / 2}$.

## Variables

$p_{n} \quad$ real power injected at bus $n$
$q_{n} \quad$ reactive power injected at bus $n$
$V^{r_{n}} \quad$ real part of the voltage at bus $n$
$v_{n}^{j_{n}} \quad$ imaginary part of the voltage at bus $n$
$V_{n} \quad$ the voltage magnitude at bus $n$
$\dot{I}_{n} \quad$ real part of the current injected at bus $n$
$i_{n} \quad$ imaginary part of the current injected at bus $n$
$i_{n} \quad$ the current magnitude of injection at bus $n$
$i^{r}{ }_{n m k}$ real part of the current on line $k$ at bus $n$ to bus $m$
$i_{n m k}$ imaginary part of the current on line $k$ at bus $n$ to bus $m$
$i_{n m k} \quad$ the current magnitude on line $k$ at bus $n$ to bus $m$

## Parameters

$c^{p}{ }_{n}\left(p_{n}\right) \quad$ cost function of real power injected by a generator at bus $n$
$c^{q} q_{n}\left(q_{n}\right) \quad$ cost function of reactive power injected by a generator at bus $n$
$c^{p l_{n}}\left(p_{n}\right) \quad$ linear cost function of real power by a generator at bus $n$
$c^{q l_{n}}\left(q_{n}\right) \quad$ linear cost function of reactive power by a generator at bus $n$
$b_{n m k} \quad$ imaginary part of the admittance matrix for line $k$ between $n$ and $m$
$g_{n m k} \quad$ real part of the admittance matrix for line $k$ between $n$ and $m$
$p^{\text {min }_{n}} \quad$ minimum required real power at bus $n$
$p^{\max _{n}} \quad$ maximum allowed real power at bus $n$
$q^{\min _{n}} \quad$ minimum required reactive power at bus $n$
$q^{\max _{n}} \quad$ maximum allowed reactive power at bus $n$
$V^{\text {min }} n_{n} \quad$ minimum required voltage magnitude at bus $n$
$V^{\max _{n}} \quad$ maximum allowed voltage magnitude at bus $n$
$i^{m a x}{ }_{n m k} \quad$ maximum allowed current magnitude on line $k$ from bus $n$ to bus $m$
3. Current-Voltage ACOPF Model

The current-voltage (IV) ACOPF formulation is used to find a set of voltages and currents at each bus and currents on each transmission line that minimize the objective function in terms of real and reactive power. More detail can be found in Cain et al (2012) and O'Neill et al (2012). The IV-ACOPF model is:
Minimize $\sum_{\mathrm{n}} c^{p_{n}}\left(p_{n}\right)+c^{q_{n}}\left(q_{n}\right)$
Subject to

$$
\begin{aligned}
& \dot{I}_{n m k}=g_{n m k}\left(V_{n}^{r}-V_{m}^{r}\right)-b_{n m k}\left(V_{n}^{j_{n}}-V_{m}^{j_{m}}\right) \\
& \ddot{i}_{n m k}=b_{n m k}\left(V_{n}^{r}-V_{m}^{r}\right)+g_{n m k}\left(V_{n}^{j}-V_{m}^{j}\right) \\
& i_{n}=\sum_{m k} i_{n m k} \\
& i_{n}=\sum_{m k} i^{j}{ }_{n m k} \\
& p_{n}=V_{n}^{r} i^{r}{ }_{n}+V_{j_{n} \dot{I}_{n}} \\
& p^{\min _{n}} \leq p_{n} \leq p^{\text {max }_{n}} \\
& q_{n}=v_{n}^{j_{n} i_{n}}-V^{r}{ }_{n} \dot{i}_{n} \\
& q^{\min _{n}} \leq q_{n} \leq q^{\text {max }_{n}} \\
& \left.\left(v_{n}^{r_{n}}\right)^{2}+\left(v_{n}^{j}\right)^{2} \leq\left(v^{\max }\right)_{n}\right)^{2} \\
& \left(V^{m i n} n\right)^{2} \leq\left(V_{n}^{r}\right)^{2}+\left(V_{n}^{j_{n}}\right)^{2} \\
& \left(\dot{r}_{n m k}\right)^{2}+\left(\ddot{j}_{n m k}\right)^{2} \leq\left(i^{\max }{ }_{n m k}\right)^{2}
\end{aligned}
$$

The objective function for test problems is generally presented as a quadratic function, but many applications require linear bid functions. The IV-ACOPF with linearized objective function program has the same constraints as the nonlinear model, but the objective function is a step function approximation of the nonlinear objective function. In solving the ACOPF models, we allow for an infeasible answer that is penalized by the amount the system is infeasible. We add $c^{P e n a l t y ~}\left(v^{r}, v^{j}, i^{r}, i^{j}, p\right.$, $q$ ) to the linearized objective function, where the quantity $x^{+}$is equal to $\max (x, 0)$, that is, if $x$ is positive, $x^{+}=x$; if $x$ is negative, then $x^{+}=0$. For example, if the real power is greater than the max, the objective function is penalized by that quantity times some cost; if it is less than or equal to the maximum, there is no penalty.

$$
\begin{aligned}
& c^{\text {Penalty }}\left(v^{\prime}, v^{j}, i^{\prime}, j^{\prime}, p, q\right)=\sum_{\text {mmk }} \operatorname{cpen}_{n}\left(V_{n}-v^{\min _{n}}\right)^{+}+\operatorname{cpen}_{n}\left(v^{\max _{n}}-v\right)^{+}+ \\
& \quad \operatorname{cpen}_{n}\left(i_{n m k}-i^{\max }{ }_{n m k}\right)^{+}+\operatorname{cpen}_{n}\left(p_{n}-p^{\max _{n}}\right)^{+}+\operatorname{cpen}_{n}\left(p^{\min _{n}-p_{n}}\right)^{+}+ \\
& \quad \text { cpen }_{n}\left(q^{\min _{n}}-q_{n}\right)^{+}+\operatorname{cpen}_{n}\left(q_{n}-q^{\max _{n}}\right)^{+}
\end{aligned}
$$

The system infeasibilities could possibly occur because the voltage is above the maximum or below the minimum levels, because the current is above the maximum level, or because real or reactive power violate maximum or minimum limits, as detailed in the penalty cost. Here we set $c p e n_{n}=10^{5}$. A problem is declared infeasible if the solution sets $c^{\text {Penalty }}$ to be greater than $10^{-3}$.

## 4. Methods

We considered two methods for creating line current magnitude constraints. In both these methods, we solved the alternating current optimal power flow model without line constraints and extracted the optimal current magnitudes of each line from the optimal solution.

In the first method, we constrained the current magnitude on each line to be a fraction (less than 1) of its optimal current magnitude in the unconstrained problem. However, this method did not always return feasible solutions. This is likely because the unconstrained optimization minimizes losses by lowering current magnitudes subject to all other constraints in the model. Therefore, it may not be feasible for all line currents to be restricted to something lower than in the unconstrained solution.

In the second method, we constrained the current magnitude on each transmission line to some fraction of the highest optimal current magnitude over all lines in the unconstrained problem. This method returned local optimal solutions (since the problem is non-convex) for some limits, but, if the current magnitude limit was too low, the solver could not find a feasible point. This current magnitude limit level varied widely depending on the test problem.

Procedure:

1. Solve the ACOPF without any thermal line constraints
2. Extract the optimal line current magnitudes $i_{n m k}{ }^{*}$ for current magnitude for line $k$ at bus $n$ to $m$.
3. Let $i^{\text {max }}=$ maximum $\left.\left\{i_{n m k}\right\}^{*}\right\}$ over all $n, m$, and $k$.
4. Solve the thermally constrained problem by including the constraint $i_{n m k} \leq f^{*} i^{\text {max }}$ for all combinations of $n, m$, and $k$ where $f$ is a parameter with $0<f<1$.

## 5. Computational Analysis

The input model data used is from the $14,30,57$, and 118 -bus IEEE test system data at http://www.ee.washington.edu/research/pstca/index.html. The generator costs come from MATPOWER (see Zimmerman et. al. 2011). The quadratic cost parameters are shown in the appendix. Where there are multiple transmission lines between two nodes, the lines are aggregated into an equivalent single line between the two nodes. The current magnitude measurement is per unit. Table 1 summarizes the test problem characteristics.

Table 1: IEEE Test System Data

| Buses | Lines | Generators |  | Demand | $V^{\max }$ | $V^{\min }$ | Best <br> Known Value* |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
|  |  | Number | Total Capacity |  |  |  | 80.81 |
| 14 | 20 | 5 | 7.72 | 2.59 | 1.06 | 0.94 | 5.745 |
| 30 | 41 | 6 | 326.80 | 42.42 | 1.10 | 0.94 | 417.4 |
| 57 | 80 | 7 | 326.78 | 235.26 | 1.06 | 0.94 | 1297 |
| 118 | 186 | 54 | 99.66 | 42.42 | 1.06 | 0.94 |  |

*Quadratic Objective, Nonlinear Constraints
Hardware. The problems were solved on an Intel Xeon E7458 server with 8 64-bit 2.4 GHz processors and 64 GB memory. Minor differences in solution times were recorded when the same problems were run at different times, but the differences were small enough to be considered background noise.
Software. The procedures were formulated in GAMS 23.6.2. The nonlinear solver used was IPOPT version 3.8.
Approach. The IV-ACOPF formulation, as described above, was used to solve the test cases shown below. For each test problem, a figure shows the impact on the line current magnitudes on test systems were examined with the current magnitude level at $75 \%, 80 \%, 90 \%$, and $100 \%$ of the maximum current magnitude level in the test problem without line current magnitude constraints. The optimal solution may be infeasible, that is, have a penalty function greater than zero. A second figure shows the line index versus the line current magnitude where the line index is sorted from lowest to highest current magnitude level. The red solid line in each graph is the chosen tight current magnitude limit and the dashed green line is the
chosen loose current magnitude limit. A cross walk from line number to the buses the line is connecting is in the appendix.
Testing Current Magnitude Constraints. From the testing described in the previous sections, the uniform rule restricting current magnitude to the same percentage of maximum current magnitude has a different impact on the different test cases.
Therefore, we picked different percentages of current magnitudes for each case and created two sets of constrained problems: tight and loose. The tight current magnitude level is near the current magnitude level where the problem becomes infeasible. The loose current magnitude level is a level that constrains the problem but is farther away from the point of infeasibility. These levels are shown in Table 2.

Table 2: Tight and loose testing levels of current magnitude constraints

|  | 14-bus | 30-bus | 57-bus | 118-bus |
| :--- | ---: | ---: | ---: | ---: |
| Low Level (Tight Constraint): <br> \% of Maximum Optimal Current magnitude: | 18.5 | 93.3 | 76.2 | 24.3 |
| High Level (Loose Constraint): <br> \% of Maximum Optimal Current magnitude: | 51.1 | 95.4 | 77.0 | 71.9 |
| Low (Tight Constraint) Current magnitude Level | 0.2264 | 0.3092 | 1.4027 | 0.9294 |
| High (Loose Constraint) Current magnitude Level | 0.6246 | 0.3162 | 1.4168 | 2.7536 |

14 -Bus Problem. In the 14-bus system when current is not constrained, one line has nearly twice the current magnitude as the next highest current line. As the current magnitude constraint is decreased, the effect on other lines is shown in figures 1 and 2. The current magnitudes that change the least under restriction are the lines with comparatively lower current magnitudes. For the loose constraint, only one current has a binding constraint. For the tight constraint, four constraints are binding or near binding.

Figure 1. 'Optimal’ 14-Bus Current Magnitudes per Line under Percent Restrictions

Figure 2. 14-Bus Optimal Current Magnitudes under the Loose and Tight Constraints.

30-Bus Problem. For the 30-bus system, the current level could not be restricted much lower than the maximum optimal current level ( 0.3314 ) before the system became infeasible. Restricting the current shifts the line current magnitudes more than in the 14-bus problem; there are many lines where current actually increases. While the difference between the tight (0.3092) and loose ( 0.3162 ) constraints is small, these restrictions do have a large impact on the resulting current through some of the lines. In both cases, only two lines have binding constraints

Figure 3. 'Optimal' 30-Bus Current Magnitudes per Line under Percent Restrictions

Figure 4. 30-Bus Optimal Current Magnitudes under the Loose And Tight Constraints.

57-Bus Problem. For the 57-bus system, the optimal solution has most of current magnitudes of half or less the highest current magnitude, similar to the 14-bus problem. While about half of the lines exhibit minimal change, the other half have currents that change significantly with the restriction. Like the 30-bus problem, the two current restrictions are close together, with 1.4027 for the loose limit and 1.4168 for the tight limit. In both cases, only two lines have binding constraints. However, even this small difference in limits greatly impacts the current on some lines.

Figure 5. 'Optimal' 57-Bus Current Magnitudes per Line under Percent Restrictions

Figure 6. 57-Bus Optimal Current Magnitudes under the Loose and Tight Constraints.

118-Bus Problem. The 118-bus system has several lines with higher currents, similar to the 30 -bus system. The current can be restricted greatly before the problem becomes infeasible. Reducing current by up to 75\% of its original optimal maximum does not have much impact on line currents except the highest ones, as seen in Figure 7. Constraining the current with the loose limit impacts the currents slightly; however, constraining the current with the tight limit has a major impact on the current magnitudes, as in Figure 8. Under the loose constraint, only one line constraint is binding. Under the tight current magnitudes, 22 of the lines have the highest permissible current under this restriction, and even lines with lower currents exhibit big differences from the unrestricted and loose current cases, both higher and lower than before.

Figure 7. 'Optimal’ 118-Bus Current Magnitudes per Line under Percent Restrictions

Figure 8. 118-Bus Optimal Current Magnitudes under Loose and Tight Constraints.

Normalized Objective Function Value as a Function of the Current Magnitude Limit
When the current magnitude is restricted, this limit is binding on at least one line. As shown in Figure 9, the different IEEE test cases exhibit infeasibility according to the solver at different percentages of their maximum current magnitude. The denominator of the normalized objective function is the objective function without constraints.

Figure 9. Normalized Objective Function versus Current Magnitude Limit

## Normalized Solution Time as a Function of the Current Magnitude Limit

As shown in Figure 10, the computational time to solve (find a local optimal solution or declare the problem infeasible) the constrained problem only seems to grow greatly when the current magnitude is restricted to $5-15 \%$ of its original value. When it is restricted to $20 \%$ or more of its original value, the added constraints do not seem to increase or decrease the computational time predictably.

Figure 10: Impact of Current magnitude Constraints on CPU Time

Effect of Current Magnitude Constraints on the Optimal Value. When binding current magnitude constraints are added to the model, the feasible region shrinks and the objective function value increases, as shown in Figures 11 and 12 and Table 3. The objective function value of the 14 -bus problem with the tight constraint is 30 percent greater. For other problems, the increases in objective function value with current magnitude constraints were 6 percent or less.

Figure 11. Value of the quadratic objective function with current magnitude constraints

Figure 12. Value of the linear objective function with current magnitude constraints

Table 3: Objective function value for each test system and constraint type

| Problem Type | Constraint type | 14-bus | 30-bus | 57-bus | 118-bus |
| :--- | :--- | ---: | ---: | ---: | ---: |
| Quadratic Objective <br> Nonlinear Constraints | Tight Constraint | 105.4 | 5.89 | 421.5 | 1364.9 |
|  | Loose Constraint | 85.3 | 5.79 | 419.2 | 1300.1 |
|  | Unconstrained | 80.8 | 5.75 | 417.4 | 1296.6 |
| Linear Objective <br> Nonlinear Constraints | Tight Constraint | 107.4 | 6.10 | 432.2 | 1388.4 |
|  | Loose Constraint | 86.5 | 5.98 | 425.5 | 1315.5 |
|  | Unconstrained | 82.8 | 5.92 | 423.8 | 1311.5 |

Effect of Current Magnitude Constraints on the Solution Time. Current magnitude constraints also impact the solution time of each test system as shown in Figures 13 and 14 and Table 4. Adding constraints at least doubles the solution time of the problem. For the 30 -bus and 118 -bus problems, the more tightly constrained problem solves faster than the less constrained problem. For the 14-bus and 118bus problems, the less constrained problem solves faster than the more constrained problem. The 57-bus and 118-bus solution time took significantly longer than the 14-bus and 30-bus systems, but solution time is not solely based on the number of buses. The linear objective function required considerably more time to solve.

Figure 13. CPU Time with current magnitude constraints of quadratic objective

Figure 14. CPU Time of the current magnitude constrained linear objective
Table 4. CPU Time for all bus systems, constraint types, and model types

| Problem Type | Constraint type | 14-bus | 30-bus | 57-bus | 118-bus |
| :--- | :--- | ---: | ---: | ---: | ---: |
| Quadratic Objective <br> Nonlinear Constraints | Tight Constraint | 0.72 | 1.80 | 8.34 | 28.95 |
|  | Loose Constraint | 0.58 | 1.94 | 7.77 | 33.33 |
|  | Unconstrained | 0.28 | 0.78 | 1.95 | 8.13 |
| Linear Objective <br> Nonlinear Constraints | Tight Constraint | 1.16 | 1.55 | 8.42 | 32.20 |
|  | Loose Constraint | 0.91 | 2.88 | 12.05 | 38.75 |
|  | Unconstrained | 0.31 | 0.48 | 0.70 | 2.61 |

## 6. Conclusions

For each test problem, one single limit is applied to all lines that makes the optimal solution without these limits infeasible. We solve the resulting problem using the IV-ACOPF formulation. For each problem we develop a 'tight' and a 'loose' constraint.

For the 14, 30, 57 and 118-bus problems, creating line current magnitude constraints for the ACOPF problem can result in infeasible problems. As one tightens the current magnitude constraints, the objective function increases gradually at first, then increases exponentially near the point of infeasibility. Different test problems exhibit different characteristics in the line current magnitude distribution and at what current magnitude level constraint the problem becomes infeasible.

The current magnitude constraints also increase the solution time, although stricter constraints do not necessarily increase the solution time more than looser constraints. For problems like this case where the problem becomes infeasible quickly, it may work well to restrict only some of the line current magnitudes rather than all of them.

Including these constraints in the ACOPF increases the solution time between 2 to 20 times and objective function up to 25 percent.
